

Docket No. AUS920030792US1

**METHOD AND APPARATUS FOR INCREASING EFFICIENCY OF DATA
STORAGE IN A FILE SYSTEM**

BACKGROUND OF THE INVENTION

1. Technical Field:

The present invention relates generally to an improved data processing system and in particular to a method and apparatus for storing data. Still more particularly, the present invention relates to a method, apparatus, and computer instructions for storing data in a file system.

2. Description of Related Art:

Data is stored in a data processing system using a file system. The file system is a mechanism used to store and retrieve files on a storage device, such as a disc. The file system defines the directory structure for keeping track of files and the path's syntax required to access those files.

Further, a file system also defines the way that files are named as well as the maximum size of a file or volume. Examples of file systems are a journal file system (JFS) and NT file system (NTFS). File systems may divide a hard disc into small units called blocks. A block is the smallest unit of storage that may be allocated. Each block in a file system is either in an allocated state or a free state. The block size may differ depending on the particular implementation. Block sizes may be, for example, 512 bytes, 1024 bytes, 2048

Docket No. AUS920030792US1

bytes, 4096 bytes, or even in some cases 64K bytes. Most modern file systems support these types of block sizes. The selection of the block size is performed at the time in which the partition for an operating system is formatted.

As machine architectures, such as processor architectures, grow beyond 32 bytes or 64 bytes, the block size that may be supported by a file system increases. For example, with a 32 byte architecture in an Intel processor from Intel Corporation, handling of input/output is efficient using 4K pages. A 64 byte architecture is efficient with 4K and greater size pages. When file systems increase block sizes, which are supported, disc space may be wasted by the storage of files that are not divisible by the block size.

The present invention recognizes that file systems with many small files result in a large amount of wasted disc space. For example, with a block size of 512 bytes, storing a 1 byte file will result in 511 bytes being wasted. In another example, a file having a size of 513 bytes would result in one block being filled with data, while a second block only contains 1 byte of total data. As a result, 511 bytes of space are wasted. As the block size grows and the number of small files grows, the amount of disc space wasted increases.

Therefore, it would be advantageous to have an improved method, apparatus, and computer instructions for managing the storage of data in file systems.

SUMMARY OF THE INVENTION

The present invention provides a method, apparatus, and computer instructions for storing data in a file system. A determination is made as to whether space is available in an inode of the file in the file system. The data is stored into the inode in response to space being available. Additionally, data for a file may be stored in a block that is partially filled with data from another file. Data for a file may be stored using either the inode or by sharing a block. Data also may be stored using both of these mechanisms.

BRIEF DESCRIPTION OF THE DRAWINGS

The novel features believed characteristic of the invention are set forth in the appended claims. The invention itself, however, as well as a preferred mode of use, further objectives and advantages thereof, will best be understood by reference to the following detailed description of an illustrative embodiment when read in conjunction with the accompanying drawings, wherein:

Figure 1 is a pictorial representation of a data processing system in which the present invention may be implemented in accordance with a preferred embodiment of the present invention;

Figure 2 is a block diagram of a data processing system in which the present invention may be implemented;

Figure 3 is a diagram illustrating a file system in accordance with a preferred embodiment of the present invention;

Figure 4 is a diagram illustrating the storage of data in components in a file system in accordance with a preferred embodiment of the present invention;

Figures 5A and **5B** are a diagram illustrating a data structure for an inode in accordance with a preferred embodiment of the present invention;

Figure 6 is a flowchart of a process for inlining user data into an inode in accordance with a preferred embodiment of the present invention; and

Figure 7 is a flowchart of a process for sharing blocks between files in accordance with a preferred embodiment of the present invention.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT

With reference now to the figures and in particular with reference to **Figure 1**, a pictorial representation of a data processing system in which the present invention may be implemented is depicted in accordance with a preferred embodiment of the present invention. A computer **100** is depicted which includes system unit **102**, video display terminal **104**, keyboard **106**, storage devices **108**, which may include floppy drives and other types of permanent and removable storage media, and mouse **110**. Additional input devices may be included with personal computer **100**, such as, for example, a joystick, touchpad, touch screen, trackball, microphone, and the like.

Computer **100** can be implemented using any suitable computer, such as an IBM eServer computer or IntelliStation computer, which are products of International Business Machines Corporation, located in Armonk, New York. Although the depicted representation shows a computer, other embodiments of the present invention may be implemented in other types of data processing systems, such as a network computer. Computer **100** also preferably includes a graphical user interface (GUI) that may be implemented by means of systems software residing in computer readable media in operation within computer **100**.

With reference now to **Figure 2**, a block diagram of a data processing system is shown in which the present invention may be implemented. Data processing system **200** is an example of a computer, such as computer **100** in

Docket No. AUS920030792US1

Figure 1, in which code or instructions implementing the processes of the present invention may be located. Data processing system **200** employs a peripheral component interconnect (PCI) local bus architecture. Although the depicted example employs a PCI bus, other bus architectures such as Accelerated Graphics Port (AGP) and Industry Standard Architecture (ISA) may be used. Processor **202** and main memory **204** are connected to PCI local bus **206** through PCI bridge **208**. PCI bridge **208** also may include an integrated memory controller and cache memory for processor **202**. Additional connections to PCI local bus **206** may be made through direct component interconnection or through add-in boards.

In the depicted example, local area network (LAN) adapter **210**, small computer system interface SCSI host bus adapter **212**, and expansion bus interface **214** are connected to PCI local bus **206** by direct component connection. In contrast, audio adapter **216**, graphics adapter **218**, and audio/video adapter **219** are connected to PCI local bus **206** by add-in boards inserted into expansion slots. Expansion bus interface **214** provides a connection for a keyboard and mouse adapter **220**, modem **222**, and additional memory **224**. SCSI host bus adapter **212** provides a connection for hard disc drive **226**, tape drive **228**, and CD-ROM drive **230**.

An operating system runs on processor **202** and is used to coordinate and provide control of various components within data processing system **200** in **Figure 2**. The operating system may be a commercially available operating system such as Windows XP, which is available from Microsoft Corporation. An object oriented programming

Docket No. AUS920030792US1

system such as Java may run in conjunction with the operating system and provides calls to the operating system from Java programs or applications executing on data processing system **200**. "Java" is a trademark of Sun Microsystems, Inc. Instructions for the operating system, the object-oriented programming system, and applications or programs are located on storage devices, such as hard disc drive **226**, and may be loaded into main memory **204** for execution by processor **202**.

Those of ordinary skill in the art will appreciate that the hardware in **Figure 2** may vary depending on the implementation. Other internal hardware or peripheral devices, such as flash read-only memory (ROM), equivalent nonvolatile memory, or optical disc drives and the like, may be used in addition to or in place of the hardware depicted in **Figure 2**. Also, the processes of the present invention may be applied to a multiprocessor data processing system.

For example, data processing system **200**, if optionally configured as a network computer, may not include SCSI host bus adapter **212**, hard disc drive **226**, tape drive **228**, and CD-ROM **230**. In that case, the computer, to be properly called a client computer, includes some type of network communication interface, such as LAN adapter **210**, modem **222**, or the like. As another example, data processing system **200** may be a stand-alone system configured to be bootable without relying on some type of network communication interface, whether or not data processing system **200** comprises some type of network communication interface. As a further

Docket No. AUS920030792US1

example, data processing system **200** may be a personal digital assistant (PDA), which is configured with ROM and/or flash ROM to provide non-volatile memory for storing operating system files and/or user-generated data.

The depicted example in **Figure 2** and above-described examples are not meant to imply architectural limitations. For example, data processing system **200** also may be a notebook computer or hand held computer in addition to taking the form of a PDA. Data processing system **200** also may be a kiosk or a Web appliance.

The processes of the present invention are performed by processor **202** using computer implemented instructions, which may be located in a memory such as, for example, main memory **204**, memory **224**, or in one or more peripheral devices **226-230**.

The present invention provides an improved method, apparatus, and computer instructions for storing data in a file system. The mechanism of the present invention solves the problem of wasted space and blocks by inlining data directly with an inode associated with the file and/or by sharing bytes left in the last block of a file between different files. An inode is a data structure or record used to store information about files. This information includes, for example, a unique number that the file system uses to identify each file, the owner and group associated with the file, the file type, a permission list, a modification time of the inode, file creation, access, and modification times, the size of the

Docket No. AUS920030792US1

file, disc address or physical location of the file on the disc.

By inlining data, data for a file is placed directly into the inode for the file. The inode of each file system may be variable in length, for example, with JFS, the inode is 512K bytes. A reserved space of 128 bytes for inlining metadata is present currently. This reserved space also is referred to as an extension area. The metadata in this area includes, for example, extended attributes and symbolic links. The mechanism of the present invention recognizes that this metadata could include the use of the actual data from the file.

Thereafter, if inlining data does not completely solve wasted space issues, unused space in a block for another file may be shared with the data from the current file. JFS, like most file systems, stores everything in fixed disc blocks. JFS allocates as many blocks for each file as needed to store the data. The last block in a file is typically only partially filled with that space being wasted.

The present invention recognizes that a file system with many small files results in a large amount of wasted disc space. As a result, the mechanism of the present invention allows for file block sharing. File block sharing makes use of unused space in the last block of each file by sharing each free group of bytes left in the block between files. In this manner, fewer blocks will include wasted or empty space, resulting in better file performance and better disc usage.

Docket No. AUS920030792US1

Turning now to **Figure 3**, a diagram illustrating a file system is depicted in accordance with a preferred embodiment of the present invention. In this example, file system **300** includes boot block (BB) **302**, super block (SB) **304**, inode list (IL) **306**, and data blocks (DB) **308**. File system process **310** includes the processes used to read and manipulate data within file system **300**.

Boot block **302** is used when the data processing system is first booted. In particular, this block contains the code to boot strap the operating system. Super block **304** contains information about the entire disc. Inode list **306** is a list of inodes, and data block **308** contains the actual data in the form of directories and files. Super block **304** contains information used to keep track of the entire file system. This information includes, for example, the size of the file system, the number of free blocks on the file system, a list of free blocks, an index to the next free block on the list, the size of the inode list, the number of freeing inodes, a list of free inodes, an index to the next free inode on the list, lock fields for free block lists and free inodes list. This type of file system is one typically used in a Unix data processing system.

The mechanism of the present invention modifies this file system to store data within the inodes in inode list **306**, as well as share space within data block **308** between different files. Each inode or entry within inode list **306** contains information, such as, the owner, the type of data block, the last modified time, the last accessed time, the last inode modified time, access permissions,

Docket No. AUS920030792US1

the number of links to the file, the size of the file, and the data blocks associated with the file. The type of inode may be a file, directory, a character device, or a block device. A value of zero in these examples indicates that the particular inode is free.

In the illustrated example, file system process **310** may store data for an inode in inode list **306** in a portion of the inode that is typically used to store metadata, such as extended attributes and symbolic links to describe the data being stored. The mechanism of the present invention uses this field to store actual data rather than metadata. Of course, other fields in an inode may be used to store data for a file, depending on the implementation.

As a result, file system process **310** is able to inline user data directly into the inode. As used herein, inlining data means to place or insert data into a space or field in an inode or file system record. This type of data storage is used in the illustrative examples in the case in which the data for a file does not completely fill a block and is small enough to fit within this reserved area.

If this amount of space is insufficient, file system process **310** may use file block sharing to make use of unused space of a data block in data block **308** for the current file. In other words, data from the current file being stored or modified is stored in unused space in a shared data block of another file.

Turning now to **Figure 4**, a diagram illustrating the storage of data in components in a file system is

Docket No. AUS920030792US1

depicted in accordance with a preferred embodiment of the present invention. In this example, file **400** represents data that is to be stored in a file system, such as file system **300** in **Figure 3**. Inode **402** is assigned to file **400** for use in identifying the data blocks in which data for file **400** is to be stored. In this example, data for file **400** is stored in data block **404**. In the illustrative example, data block **404** is insufficient in size to store all of the data for file **400**. As a result, any additional data for this file may be stored in extended area **406** of inode **402**. If the space available in extended area **406** is insufficient to store the remaining data file **400**, file block sharing may be employed to store additional data in another block allocated for another file.

In this illustrative example, file **407** has its data stored in block **408** and in section **410** of block of **412**. As shown, block **412** is used as a shared block. The data from file **407** fills up all of block **408**, but occupies only section **410** in block **412**. As a result, section **414** of block **412** is unused. Normally, this unused space in block **412** is wasted. Through file block sharing, data for file **400** may be stored within section **414**. In this particular example, only portion **414** of data block **412** is needed to store the remaining data from file **400**. Any additional unused space in data block **412** may be shared among other files. In this manner, wasted disc space for files is eliminated for those files that are not divisible by the block size used in the file system. With respect to information stored in the inode, a

Docket No. AUS920030792US1

portion of the field is used to identify whether user data is inlined into the inode. Further, pointers may be included in the inode in which the pointers point to a shared block. Also, an offset may be used to identify the beginning of the data in the shared block along with a length that is used to identify the amount of data in the shared block.

Turning now to **Figures 5A** and **5B**, a diagram illustrating a data structure for an inode is depicted in accordance with a preferred embodiment of the present invention. Inode **500** is an example of an inode in a file system, such as inode **402** in **Figure 4**. In this example, inode **500** contains base area **502**, index table **504**, and extended area **506**. Extended area **506** is employed to inline different file system objects. Two of these objects are symbolic links and extended attributes.

A symbolic link is a type of file that contains a path name to another file. The file type entry in the file's inode indicates that the entry is a symbolic link. When an attempt is made to access a symbolic link with a text editor or other program, the operating system kernel redirects the program to the file indicated by the symbolic link's path name. An extended attribute contains a name and value. Applications may attach additional information to a file object in the form of an extended attribute. A file object may have more than one extended attribute. Extended attributes associated with the file object are not a part of the file object's data. These attributes are maintained separately and managed by the file system that manages the object.

Docket No. AUS920030792US1

The mechanism of the present invention adds an additional object shown in line **508** to inline user data. This portion of inode **500** may be used to store data for a file assigned to inode **500**.

Turning now to **Figure 6**, a flowchart of a process for inlining user data into an inode is depicted in accordance with a preferred embodiment of the present invention. The process illustrated in **Figure 6** may be implemented in a file system process, such as file system process **310** in **Figure 3**.

The process begins by determining whether the inode space for the file is already used (step **600**). This space is the extended area portion of the inode. This area may be used by other information, such as a symbolic link or extended attributes. If the inode space is not already used, then a determination is made as to whether the file size is divisible by the block size (step **602**).

If the file size is not divisible by the block size, then the data is inlined into the inode (step **604**). Thereafter, a flag is updated to show that user data has been inlined (step **606**) with the process terminating thereafter. In the inode, the mode field in the inode is used to determine if user data is inlined into the inode.

With reference again to step **602**, if the file size is divisible by the block size, data is not inlined because blocks will not be wasted when storing user data. With reference again to step **600**, if the inode space is already used, the process also terminates because no space is present for storing user data.

Docket No. AUS920030792US1

Turning next to **Figure 7**, a flowchart of a process for sharing blocks between files is depicted in accordance with a preferred embodiment of the present invention. The process illustrated in **Figure 7** may be implemented in a file system process, such as file system process **310** in **Figure 3**.

The process begins by determining whether the file size is divisible by the block size (step **700**). If the file size is not divisible by the block size, an inline process is executed (step **702**). Step **702** may be performed using the process illustrated in **Figure 6** above. A determination is then made as to whether inlining of data was successful (step **704**).

If all of the data was inlined in step **704**, the process terminates. Otherwise, the data that is not inlined is placed in a shared block. A determination is made as to whether a block with sufficient free bytes to store the data is present (step **706**). If such a block is found, the data is placed into the identified block (step **708**).

Thereafter, a flag is updated to indicate block sharing (step **710**). In the inode, the mode field in the inode is used to determine if the last bytes of the user data is in a shared block.

Further, data structures describing available blocks that can be shared are updated (step **712**) with the process terminating thereafter. These data structures contain information describing available blocks that may be shared by reducing the number of bytes free. A list of free shared blocks is kept so the file system can find

Docket No. AUS920030792US1

a shared block that contains enough free bytes to place the user data in. Once the block is full it is taken off the list of free shared blocks. The free shared blocks structure has the following information: block number, free bytes in the block, and pointer to the next block.

With reference again to step **706**, if a block with sufficient free bytes is absent, then a block is created or allocated (step **714**), and the data is stored in the created block (step **716**) with the process terminating thereafter.

With reference again to step **704**, if inlining is successful in storing all of the data in step **704**, the process terminates. The process also terminates if the file size is divisible by the block size because blocks will not be wasted by performing this process.

Thus, the present invention provides an improved method, apparatus, and computer instructions for storing data in a file system. The mechanism of the present invention may store data within an inode. Further, the mechanism of the present invention also allows for the sharing of blocks between different files. In this manner, disc space utilization is improved because of the reduction of blocks with unused space.

It is important to note that while the present invention has been described in the context of a fully functioning data processing system, those of ordinary skill in the art will appreciate that the processes of the present invention are capable of being distributed in the form of a computer readable medium of instructions and a variety of forms and that the present invention

Docket No. AUS920030792US1

applies equally regardless of the particular type of signal bearing media actually used to carry out the distribution. Examples of computer readable media include recordable-type media, such as a floppy disc, a hard disc drive, a RAM, CD-ROMs, DVD-ROMs, and transmission-type media, such as digital and analog communications links, wired or wireless communications links using transmission forms, such as, for example, radio frequency and light wave transmissions. The computer readable media may take the form of coded formats that are decoded for actual use in a particular data processing system.

The description of the present invention has been presented for purposes of illustration and description, and is not intended to be exhaustive or limited to the invention in the form disclosed. Many modifications and variations will be apparent to those of ordinary skill in the art. The embodiment was chosen and described in order to best explain the principles of the invention, the practical application, and to enable others of ordinary skill in the art to understand the invention for various embodiments with various modifications as are suited to the particular use contemplated.
